Prepared by the **COMMUNICABLE DISEASE CENTER** **MEIrose 4-5131**

For release February 3, 1961

Atlanta 22, Georgia

Vol. 10, No. 4

Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended January 28, 1961

Influenza — No reports of epidemic influenza or recent influenza virus isolations have been received during the current season from any part of the United States. During the past six weeks, influenza and pneumonia deaths in this country have remained slightly above normal levels, but no significant excess mortality has occurred.

Hepatitis — A total of 1,856 cases was reported for the week ending January 28, 1961, a figure almost identical with last week's total of 1,829 cases. Hepatitis cases for 1961 remain high above comparative totals of the past 9 years. Localized outbreaks are occurring in most States

and CDC has been notified this week of specific outbreaks in Clark County, Kentucky; Franklin County, Illinois; and Duchesne County, Utah.

EPIDEMIOLOGICAL REPORTS

Hepatitis — Macy, Nebraska

Dr. Holman R. Wherritt, Medical Officer in Charge, Public Health Indian Hospital in Winnebago, Nebraska, has reported an outbreak of infectious hepatitis among Omaha Indians. A total of 25 cases have occurred since

Table 1. Cases of Specified Notifiable Diseases, United States

August in and around Macy, a town of 732 population. Only 2 cases were reported among these Indians between 1957 and August 1960. All of the cases were jaundiced, and all were mild with the exception of two white women — a nurse who treated cases at the Indian hospital and a minister's wife who taught Sunday school; their courses necessitated longer convalescent periods. The figure below shows cases by week of onset:

HEPATITIS, OMAHA INDIAN RESERVATION

Fifteen had onset in December and 7 in January. Two peaks separated by about 30 days are discernible in December and January. The ages of the cases showed a distinct pattern. Six were preschool age, 17 were 5–9 years old, 1 was in the 10–14 age group, and 5 were 20 or above. The paucity of cases over 10 years of age is noteworthy. Fourteen of the children attended a single elementary school. All were Indians with the exception of the two white women. A careful study of the cases points to the person-to-person route as the predominant means of spread. All household contacts of cases occurring after November 15 have been given immune serum globulin and subsequent cases have not occurred in these family members.

Typhoid – Colorado

One week ago Colorado reported three typhoid cases; during the entire year 1961, a total of one case was reported. Dr. Cecil Molohan, Chief, Division of Epidemiology, Colorado State Department of Public Health, has informed us that the current cases were apparently unrelated. Two cases were adults — the first, a 33-year old man developed symptoms in mid-December. He had been traveling in South America and was hospitalized with compatible symptoms and elevated H and O agglutinin titers. No culture was taken before treatment with chloramphenicol was initiated. The second, a 29-year old man recently returned from Mexico, developed symptoms on January 10 and was found to have positive stools for *S. typhosa*. The third case, a three year old girl, had onset of symptoms on January 12 and stool cultures were

positive. A most interesting background to this case is being investigated. The girl's grandmother, who has a history of having typhoid fever at age 11, came to live in the home of the patient in November. Late in the same month the grandmother was hospitalized with gallstone ileus and in mid-January (before cultures could be taken) she had a cholecystectomy. The girl's mother was hospitalized December 27, 1960, with fever, chills, and diarrhea and a gram-negative bacillus was isolated from her blood. She was started on chloramphenicol prior to further cultures. It appears that the grandmother may have unknowingly affected both her daughter and granddaughter.

Poliomyelitis – Puerto Rico

A preliminary total of 497 paralytic poliomyelitis cases occurred in Puerto Rico during 1960. Of these, 433 or 89 percent had spinal paralysis with the remaining 11 percent having bulbar or bulbo-spinal involvement. The epidemic began late in January and reached a peak during the week ending June 11. The first case resided in the Ponce area and later cases occurred throughout the island with 68 of 76 municipalities having at least one case. The cases are shown in the following table by age and vaccination status.

Paralytic Poliomyelitis by Age and Vaccination Status
Puerto Rico, 1960 – Preliminary Data

Age	Vaccination Status						Total	%*
	0	1	2	3	4+	Unk		
<1	85	7	5	2	0	2	101	20.3
1	110	4	3	3	0	1	121	24.3
2	71	2	4	2	1	2	82	16.5
3	56	10	4	5	0	2	77	15.5
4	39	1	3	4	0	0	47	9.5
5-9	38	4	4	11	0	1	58	11.6
10-14	3	0	1	0	0	0	4	0.8
15+	4	0	1	1	0	1	7	1.4
Total	406	28	25	28	1	9	497	100.0
%*	83.2	5.7	5.1	5.7	0.2		100.0	

* Specified cases

It is evident that the epidemic involved predominantly unvaccinated preschool children; 86 percent of the cases were under 5 years of age. Only 6 percent of the cases received three or more doses of vaccine while 83 percent had not had one dose.

(Submitted by Dr. Manuel Feliberti, Epidemiologist, Puerto Rico Department of Health)

The chart shows the number of deaths reported for 117 major cities of the United States by week for the current year, a 5-week moving average of these figures plotted at the central week, and an adjusted average for comparison. For each region the adjusted average was computed as follows: From the total deaths reported each week for the years 1956-1960, 3 central figures were selected by eliminating the highest and lowest figure reported for that week. A 5-week moving average of the arithmetic mean of the 3 central figures was then computed with adjustment to allow for population growth in each region. The average value of the regional increases was 2 percent which was incorporated in the adjusted average shown in the chart.

Table 4 shows the number of death certificates re-

ceived during the week indicated for deaths that occurred in selected cities. Figures compiled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received from a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

Botulism — Minnesota (Follow-up Report)

In September 1960 (Volume 9, Number 38) the Minnesota Department of Health supplied preliminary information on two fatal cases of botulism. Death followed within two days after consumption of smoked fresh water fish marketed in vacuum packed plastic bags. In a follow-up letter, Dr. Karl R. Lundeberg, Commissioner of Health, Minneapolis, reports that the early impression, that the botulinus toxin responsible for the two deaths was either type A or B was erroneous. "Subsequent studies by Dr. C. E. Dolman, University of Vancouver, Dr. G. M. Dack, University of Chicago, and the Pure Food and Drugs Laboratory, Washington, demonstrated that this outbreak was due to botulinus toxin type E. *Cl. botulinum*, type E organisms were isolated from the smoked fish by Dr. Dolman. It is interesting to note that type E is reported to grow and elaborate toxin at considerably lower temperatures than the more common types, A and B. In these deaths, the question of refrigeration assumed special importance because it was claimed that refrigeration was continuously maintained up to the time of consumption of the fish even though the accident happened during a spell of unusually hot weather." These two cases are thought to represent the first report in the United States of botulism due to type E toxin ascribed to fresh water fish.

INTERNATIONAL NOTES

Influenza — Dr. Edward J. O'Rourke, Epidemiologic Consultant, Europe, U.S. Public Health Service, American Embassy, London, reports that influenza continues in Great Britain where cases are widespread in the Midland and Northwestern Regions and beginning to occur in London. Many isolations of the A₂ influenza virus strain have been made. England and Wales report 358 influenza deaths for the week ending January 21, 1961, which compares with 32 deaths for the corresponding week in 1960. Pneumonia and bronchitis deaths have remained above the 1960 levels for the past six weeks. Professor Patrick N. Meenan, University College, Dublin, has reported that influenza is widespread in Dublin and appears also, from preliminary information, to be occurring in all parts of that country. Viruses isolated from patients in the Dublin area are of the A₂ strain. There is no reported influenza on the European Continent.

The WHO Weekly Epidemiological Record, Number 4, January 27, 1961 mentions a small outbreak of virus B influenza which occurred in December 1960, in a class of a primary school in Tokyo, Japan. An associated press release dated January 27, Tokyo, indicates that influenza outbreaks in that city have resulted in widespread closing of schools.

QUARANTINE MEASURES

Immunization Information for International Travel

No Changes Reported

SOURCE AND NATURE OF MORBIDITY DATA

These provisional data are based on reports to the Public Health Service from the health departments of each State and Puerto Rico. They give the total number of cases of certain communicable diseases reported during the week usually ended the preceding Saturday. Total figures for the United States and the Pacific Division include data for the States of Alaska and Hawaii. Cases of anthrax, botulism, and rabies in man are not shown in table 2, but a footnote to table 1 shows the States reporting these diseases. When diseases of rare occurrence are reported by a State (cholera, dengue, plague, louse-borne relapsing fever, smallpox, louse-borne epidemic typhus, and yellow fever) this is noted below table 1.
